Units of p-power order in principal p-blocks of p-constrained groups

Martin Hertweck ⋆

Universität Stuttgart, Fachbereich Mathematik, IGT, 70550 Stuttgart, Germany

Abstract

Let G be a finite group having a normal p-subgroup N that contains its centralizer $\mathrm{C}_G(N)$, and let R be a p-adic ring. It is shown that any finite p-group of units of augmentation one in RG which normalizes N is conjugate to a subgroup of G by a unit of RG, and if it centralizes N it is even contained in N.

Key words: principal block, torsion unit, permutation lattice, p-constrained group

1 Introduction

This paper grew out of an attempt to understand more fully part of a theorem due to Roggenkamp and Scott (see [10, Theorem 6], [16,17], [11, Theorem 19]) about conjugacy of certain finite p-subgroups in the group of units of a p-adic group ring. The theorem in question, by now called the F*-Theorem, is stated below together with references where a detailed account on its proof can be found (with the result from Section 2 of the present paper being relevant).

Some of the interesting aspects of the group of units of a group ring SG of a finite group G concern its finite subgroups, in particular when the coefficient ring S is a G-adapted ring, i.e., an integral domain of characteristic zero in which no prime divisor of the order of G is invertible. Below, a few well known results in this case are listed. Note that it suffices to consider only the group of units $\mathrm{V}(SG)$ consisting of units of augmentation one. For $u \in \mathrm{V}(SG)$, we say that u is a trivial unit if $u \in G$, and the trace of u is its 1-coefficient (with respect to the basis G). Let S be a G-adapted ring. Then (see [15], [8] or [18]):

(a) a non-trivial unit of SG of finite order has trace zero;
(b) the order of a finite subgroup of $\mathrm{V}(SG)$ divides the order of G;
(c) a central unit of finite order is a trivial unit.

Limiting attention only to finite p-subgroups in the group of units, one might ask whether comparable results hold with S replaced by the ring $\mathbb{Z}_p$ of p-adic integers. However, (a) and (b) does not carry over, even not if $\mathbb{Z}_pG$ consists of a single block only (cf. [14, Section XIV]). Imposing additional conditions one might also ask how certain finite p-subgroups are embedded in $\mathrm{V}(\mathbb{Z}_pG)$. If, for example, attention is directed to the principal block B of $\mathbb{Z}_pG$, a Sylow p-subgroup P of G is identified with its projection on B, and α is an augmented automorphism of B, then the question whether P is conjugate by a unit of B to its image $P\alpha$, is part of Scott's "defect group (conjugacy) question" (see [16, p. 267], [17]). For p-groups G, this question was answered in the affirmative by Roggenkamp and Scott [13].

Here, the following two theorems are proved. In both we assume that G has a normal p-subgroup N satisfying $\mathrm{C}_G(N) \leq N$. By definition, this means that G is p-constrained and $\mathrm{O}_{p'}(G) = 1$ (see [6, VII, 13.3]).

Throughout the paper, R denotes a p-adic ring, that is, the integral closure of the p-adic integers $\mathbb{Z}_p$ in a finite extension field of the p-adic field $\mathbb{Q}_p$. (Then R is a complete discrete valuation ring.) Note that by our assumption on G, the group ring RG will consist of a single (principal) block only (see [6, VII, 13.5]).

Theorem A. *Suppose that G has a normal p-subgroup N that contains its centralizer $\mathrm{C}_G(N)$. Then any finite p-group in $\mathrm{V}(RG)$ which normalizes N is conjugate to a subgroup of G by a unit of RG.*

Theorem B. *Suppose that G has a normal p-subgroup N that contains its centralizer $\mathrm{C}_G(N)$. Then any finite p-group in $\mathrm{V}(RG)$ which centralizes N is contained in N.*

The proofs are somewhat complicated by the fact that we do not know in advance that RG is free for the "multiplication action" of the finite p-group under consideration (taking this for granted, Theorem A should be part of the F*-Theorem). Section 2 contains some preparatory results needed for the handling of the case $p = 2$. Theorems A and B are proved in Section 3. The bimodule arguments used there are inspired by [10, p. 231]. The proof depends heavily on the strong results of Weiss on p-permutation lattices (see [20,21], [12]). That these results can be applied rests upon the "Ward–Coleman Lemma." Coleman's contribution [1] is well known, but the first version of the lemma appears in an article of Ward [19] as a contribution to a seminar run by Richard Brauer at Harvard. See also [15, Proposition 1.14], [7, 2.6 Theorem]. Actually, for its proof it is only needed that p is not invertible in the commutative ring R.

Ward–Coleman Lemma. *Let H be a p-subgroup of the finite group G. Then* $\mathrm{N}_{\mathrm{V}(RG)}(H) = \mathrm{N}_G(H) \cdot \mathrm{C}_{\mathrm{V}(RG)}(H)$. $\square$

A consequence of Theorem B deserves explicit mention.

Corollary. *Suppose that G has a normal p-subgroup N that contains its centralizer $\mathrm{C}_G(N)$. Then each central unit of (finite) p-power order in $\mathrm{V}(RG)$ is a trivial unit, i.e. contained in $\mathrm{Z}(G)$.*

It is not known whether a corresponding result holds for the principal block of an arbitrary (non-solvable) group. Progress in this direction might lead to applications in finite group theory, through Robinson's work [9] on odd analogues of Glauberman's Z^*-Theorem.

Finally, we state the theorem of Roggenkamp and Scott.

F*-Theorem. *Let G be a finite group having a normal p-subgroup N that contains its centralizer $\mathrm{C}_G(N)$. If α is an automorphism of RG stabilizing both the augmentation ideal $\mathrm{I}_R(G)$ and the ideal $\mathrm{I}_R(N)G$, then the groups G and G^α are conjugate by a unit of RG.*

The first step of the proof consists in showing that N and N^α are conjugate by a unit of RG, so that $N = N^\alpha$ can be assumed (details of sketch proof in [10] are given in [4, Lemma 4.1]). Then the image P^α of a Sylow p-subgroup P of G normalizes N, and by Theorem A one can even assume that $P = P^\alpha$. Now it can be shown that there exists an automorphism ρ of G such that the composition $\alpha\rho$ fixes the elements of P, which implies that $\alpha\rho$ is an inner automorphism of RG (see [3] for a published account).

2 (Mod 2) conjugacy for involutions

The main result of this section is Proposition 5, which will be used in conjunction with Proposition 1 to prove in the next section Lemma 7 for $p = 2$, which then allows application of Weiss' theorem on p-permutation lattices in the proof of Theorem A and B.

We continue to denote by G a finite group and by R a p-adic ring. For a subgroup H of G, let $\mathrm{I}_R(H)$ denote the augmentation ideal of RH, i.e. the R-span of the elements $h - 1$ ($h \in H$). If H is a normal subgroup, $\mathrm{I}_R(H)G$ is the kernel of the natural map $RG \to RG/H$. For any subset T of G, let $R[T]$ denote the R-span of the elements of T.

The Ward–Coleman Lemma suggests a closer investigation of $\mathrm{C}_{\mathrm{V}(RG)}(N)$, for G and N as in Theorems A and B.

Proposition 1. *Suppose that G has a normal p-subgroup N that contains its centralizer $\mathrm{C}_G(N)$. Then the following holds.*

(a) $\mathrm{C}_{RG}(N) \subseteq R + \mathrm{I}_R(N)G + pRG$.
(b) *Assume that $p = 2$ and set $\bar{G} = G/\mathrm{O}_2(G)$. If a subset T of G is chosen such that $\bar{T}$ is the set of involutions in $\bar{G}$, then*

$$\mathrm{C}_{RG}(N) \subseteq R + \mathrm{I}_R(\mathrm{O}_2(G))G + 4RG + 2R[T].$$

PROOF. For $g \in G$ define its "N-class sum" $\mathscr{C}_g^N$ to be the sum (in RG) of the distinct g^x, $x \in N$. Note that the N-class sums form an R-basis of $\mathrm{C}_{RG}(N)$. Let $g \in G$. If $\mathrm{C}_N(g) = N$, then $g \in \mathrm{C}_G(N) \leq N$ and $\mathscr{C}_g^N = g$, and if $|N : \mathrm{C}_N(g)| = p^a > 1$, then $\mathscr{C}_g^N \in p^a g + \mathrm{I}_R(N)G$. Hence (a) holds. Set $N^* = N/\Phi(N)$, the quotient of N by its Frattini subgroup $\Phi(N)$. The group G acts by conjugation on the elementary abelian group N^*. Since N is not centralized by p'-elements of $G \setminus \{1\}$, the kernel K of this operation is a p-group (see [5, III, 3.18]), whence contained in $\mathrm{O}_p(G)$. Now let $p = 2$ and suppose that $|N : \mathrm{C}_N(g)| = 2$ for some $g \in G$. Then $|N^* : \mathrm{C}_{N^*}(g)| \leq 2$, so $g^2 \in K \leq \mathrm{O}_2(G)$ and $\mathscr{C}_g^N \in R + \mathrm{I}_R(\mathrm{O}_2(G))G + 2R[T]$, which completes the proof of (b). □

In particular, we are led to consider units u of order p in RG/N which map to 1 in $(R/pR)(G/N)$. The following well known lemma (cf. [21, Lemma (53.3)]) shows that this is actually only a matter for $p = 2$.

Lemma 2. *Let p be an odd prime. Then the group of units in $1 + pRG$ has no p-torsion.*

PROOF. Suppose that u is a unit of order p in $u \in 1 + pRG$ and write $u = 1 + p^a x$ with $a \in \mathbb{N}$ such that $x \in RG \setminus pRG$. Writing out the binomial expansion for $(1+p^a x)^p = 1$ and solving for x, we get $p \cdot p^a x = -\sum_{n=2}^{p} \binom{p}{n} p^{an} x^n$. But the right-hand side has a factor $p \cdot p^{2a}$ since $p > 2$. This contradiction proves the lemma. □

The reader might wish to convince himself that the statement of the lemma does not hold for $p = 2$, even if u is assumed to have augmentation one.

As usual, we let $[RG, RG]$ denote the additive commutator of RG, defined by

$$[RG, RG] = {}_R\langle g^h - g \mid g, h \in G\rangle = \{xy - yx \mid x, y \in RG\}.$$

The following formulas are well known (see, for example, [18, Lemma (7.1)]). We write K for the quotient field of R, let $a_1, \ldots, a_l \in RG$ and $n \in \mathbb{N}$.

$$[KG, KG] \cap RG = [RG, RG] \tag{1.1}$$
$$[RG, RG]^p \subseteq pRG + [RG, RG] \tag{1.2}$$
$$(a_1 + \cdots + a_l)^{p^n} \equiv a_1^{p^n} + \cdots + a_l^{p^n} \bmod pRG + [RG, RG] \tag{1.3}$$

Let $G_{p'}$ denote the set of p'-elements of G. It follows immediately from (1.2) and (1.3) that for large enough $n \in \mathbb{N}$ (it suffices that p^n is the order of a Sylow p-subgroup of G) and any $x \in RG$,

$$x^{p^n} \in pRG + [RG, RG] + R[G_{p'}]. \tag{1.4}$$

Fix some $c \in G$. We define

$$[RG]^{1-c} = {}_R\langle g - g^c \mid g \in G\rangle = \{x - x^c \mid x \in RG\}.$$

Set $C = \langle c\rangle$. If RG is considered as a C-module for the "conjugation action" $m \cdot c = c^{-1}mc$ ($m \in RG$), then $[RG]^{1-c}$ is the image of the map $RG \xrightarrow{\cdot(1-c)} RG$. Since $\mathrm{H}^1(C, RG) = 0$ (see [13, (1.4.1) Proposition]), $[RG]^{1-c}$ is also the kernel of the map $RG \xrightarrow{\cdot\widehat{C}} RG$ where $\widehat{C}$ denotes the sum of the elements in C. In particular, it follows that

$$[KG]^{1-c} \cap RG = [RG]^{1-c}. \tag{2}$$

We remark that $[RG]^{1-c}$ is invariant under left (and right) multiplication with c. Also, if $c^2 = 1$, then $([RG]^{c-1})^2 \subseteq 2RG + [RG]^{c-1}$ in analogy to (1.2) holds since $(g - g^c)(h - h^c) = gh + (gh)^c - g^ch - (g^ch)^c$ for all $g, h \in G$.

Lemma 3. *Let $c \in G$ and $u \in \mathrm{V}(RG)$ be 2-elements. Assume that $c^2 = u^2$ and $c^{-1}u = 1 + 2f$ for some $f \in RG$. Then*

(a) $f + f^2 \in 2RG + [RG]^{1-c}$;
(b) $f + f^{2^n} \in 2RG + [RG, RG]$ *for all* $n \in \mathbb{N}$;
(c) $f \in 2RG + [RG, RG] + R[G_{2'}]$.

PROOF. Squaring the equation $c^{-1}u = 1+2f$ yields $1+4(f+f^2) = (c^{-1}u)^2$, so $4(f + f^2)u^{-1}c = c^{-1}u - u^{-1}c$. Now $c^{-1}u = cu^{-1}$ since $c^2 = u^2$, and it follows that $4(f + f^2)u^{-1}c = cu^{-1} - (cu^{-1})^c \in [RG]^{1-c}$. By (2), and since $c^{-1}u \in 1 + 2RG$, (a) follows. Now (b) follows inductively from (1.2) and $f + f^{2^n} = (f + f^2) + (f + f^{2^{n-1}})^2 - 2f(f + f^{2^{n-1}})$. Part (c) follows from (b) and (1.4). $\square$

Let T_2 be the set of involutions in G.

Lemma 4. *If $x \in R[T_2] \cap \mathrm{I}_R(G)$ then $x^2 \in (R[G \setminus T_2] \cap [RG, RG]) + 2RG$.*

PROOF. Write $x = \sum_{s \in T_2} r_s(s-1)$ with $r_s \in R$ for all $s \in T_2$. Then

$$x^2 = \sum_{s \in T_2} r_s^2 (s-1)^2 \; + \sum_{\substack{\{s,t\} \subseteq T_2 \\ s \neq t}} r_s r_t ((s-1)(t-1) + (t-1)(s-1)).$$

Let $s, t \in T_2$. Then $(s-1)^2 = 2(1-s) \in 2RG$ and

$$\begin{aligned} &(s-1)(t-1) + (t-1)(s-1) \\ &\quad = 2(1-s-t+st) - st + ts \\ &\quad \in \begin{cases} 2RG & \text{if } [s,t] = 1, \\ 2RG + (R[G \setminus T_2] \cap [RG, RG]) & \text{otherwise.} \end{cases} \end{aligned}$$

This proves the lemma. $\square$

It is evident that up to now, letting R be a p-adic ring was unnecessarily restrictive, but finally we shall use results of Weiss on permutation modules to prove:

Proposition 5. *Suppose that $p = 2$, so that R is a 2-adic ring, and let $c \in G$ and $u \in \mathrm{V}(RG)$ be 2-elements with $c^2 = u^2$ and $c^{-1}u = 1 + 2f$ for some $f \in 2RG + R[T_2] + R$. Then c and u are conjugate in the units of RG.*

PROOF. By Lemma 3(c), $f \in 2RG + [RG, RG] + R[G_{2'}]$. Compared with $f \in 2RG + R[T_2] + R$, it follows that $f \in 2RG + (R[T_2] \cap [RG, RG]) + R$. Taking augmentation gives $f \in 2RG + (R[T_2] \cap [RG, RG])$, so that by Lemma 4, $f^2 \in 2RG + (R[G \setminus T_2] \cap [RG, RG])$. By Lemma 3(a), $f + f^2 \in 2RG + [RG]^{1-c}$. The last three equations show that

$$f \in 2RG + [RG]^{1-c}. \tag{3}$$

Let C be a cyclic group with generator x of order the maximum of the orders of c and u. Consider RG as an RC-lattice, the action of x given by $m \cdot x = c^{-1}mu$ for all $m \in RG$. A 1-cocycle $\beta : C \to RG$ is defined by $\beta(x) = f = (c^{-1}u - 1)/2$. Notice that c and u are conjugate in the units of RG if β is a 1-coboundary: For if $\beta(x) = m - c^{-1}mu$ for some $m \in RG$, then $v = 1 + 2m$ is a unit in RG (see [2, (5.10)]) and $u = c^v$. The exact sequence $0 \longrightarrow RG \xrightarrow{2} RG \xrightarrow{-} \overline{RG} \longrightarrow 0$ has cohomology exact sequence

$$\ldots \longrightarrow \mathrm{H}^1(C, RG) \xrightarrow{2} \mathrm{H}^1(C, RG) \xrightarrow{-} \mathrm{H}^1(C, \overline{RG}) \longrightarrow \ldots$$

By [21, Theorem (50.2)], RG is a monomial lattice for C over R, so that 2 annihilates $\mathrm{H}^1(C, RG)$ by [21, Lemma (53.1)]. Hence the cohomology exact sequence implies that $\mathrm{H}^1(C, RG) \xrightarrow{-} \mathrm{H}^1(C, \overline{RG})$ is injective. By (3), the class of β maps to zero under this map; hence β is a 1-coboundary, and c and u are conjugate in the units of RG. $\square$

3 Proof of the theorems

From now on, G will be a finite group which has a normal p-subgroup N containing its centralizer $\mathrm{C}_G(N)$. Still, R is a p-adic ring. Let Q be a finite p-subgroup of $\mathrm{V}(RG)$ containing N as a normal subgroup. We set $M = RG$ and consider M as $R(G \times Q)$-module, the action given by $m \cdot r(g, x) = g^{-1}rmx$ for all $g \in G$, $x \in Q$, $r \in R$ and $m \in M$. We shall write, for example, $M_{G\times 1}$ for the restriction of M to G (acting from the left).

We will need the following indecomposability criterion which is proved in greater generality in [10, p. 231]. For convenience of the reader, the (short) proof is included.

Lemma 6. *As $R(G \times N)$-module, M is indecomposable.*

PROOF. Any endomorphism of $M_{G\times 1}$ is given by right multiplication with some element of RG, so $\mathrm{End}_{R(G\times N)}(M) \cong \mathrm{C}_{RG}(N)$. The radical quotient $\mathrm{C}_{RG}(N)/\mathrm{rad}(\mathrm{C}_{RG}(N))$ is isomorphic to $\mathrm{C}_{kG}(N)/\mathrm{rad}(\mathrm{C}_{kG}(N))$ where k denotes the residue class field of R (see [2, (5.22)]), and the latter quotient is isomorphic to k by Proposition 1(a) since $\mathrm{I}_k(N)G$ is nilpotent (see [2, (5.26)]). Hence $\mathrm{End}_{R(G\times N)}(M)$ is local, and M is indecomposable (see [2, (6.10)]). $\square$

By the Ward–Coleman Lemma, we may fix (and do) for each $x \in Q$ some $g_x \in G$ such that $g_x^{-1}x \in \mathrm{C}_{\mathrm{V}(RG)}(N)$. Set $U = \langle g_x \mid x \in Q\rangle \leq G$. Note that for all $x, y \in Q$ we have $(g_xg_y)^{-1}xy = (g_y^{-1}y)(g_x^{-1}x)^y \in \mathrm{C}_{\mathrm{V}(RG)}(N)$. Since $\mathrm{C}_G(N) \leq N$, it follows that $x \mapsto g_xN$ defines a surjective homomorphism $Q \to UN/N$. We set $F = \mathrm{O}_p(G)$ (the Fitting subgroup of G) and $\bar{G} = G/F$. We shall extend the bar convention when writing $\bar{m}$ for the image of m in RG under the natural map $RG \to R\bar{G}$.

Lemma 7. *Let $x \in Q$. Then $\bar{x} \in \bar{g_x} + pR\bar{G}$. Further, if $g_x \in F$ then $\bar{x} = 1$. In other words, $\bar{x} \mapsto \bar{g_x}$ defines an isomorphism $\bar{Q} \to \bar{U}$, and $\bar{Q}$ maps onto $\bar{U}$ under the natural map $R\bar{G} \to (R/pR)\bar{G}$.*

PROOF. Let $x \in Q$. Since x has augmentation one, $\bar{x} \in \bar{g_x} + pR\bar{G}$ by Proposition 1(a). Now assume that $g_x \in F$ and, by way of contradiction, that $\bar{x}$ has order p. Then $p = 2$ by Lemma 2, and by Proposition 1(b), $\bar{x} = \bar{g_x}^{-1}\bar{x} \in R + 4R\bar{G} + 2R[\bar{T}]$ where $\bar{T}$ is the set of involutions in $\bar{G}$. Hence we may apply Proposition 5 (to the group $\bar{G}$, with $c = 1$ and $u = \bar{x}$) to conclude that $\bar{x} = 1$, a contradiction. The lemma is proved. $\square$

The next lemma is the place where Weiss' theorem obviously comes into play. For a subgroup H of G we shall write $\widehat{H}$ for the sum of its elements in RG. Let P be a Sylow p-subgroup of G.

Lemma 8. *$M_{P\times Q}$ is a permutation lattice for $P \times Q$ over R.*

PROOF. First, we consider the module $\widehat{F}M_{1\times Q}$ which is isomorphic to $R\bar{G}$ with Q acting by right multiplication via $Q \to \bar{Q}$. Write $\bar{G}$ as a disjoint union $\bar{G} = \bigcup_i \bar{h_i}\bar{U}$ with $h_i \in G$, and set $B = \bigcup_i \{\bar{h_i}\,\bar{x} \mid x \in Q\}$. By Lemma 7, B reduces modulo $pR\bar{G}$ to the canonical basis $\bar{G}$ of $(R/pR)\bar{G}$, and $|B| = |\bar{G}|$. Thus B is an R-basis of $R\bar{G}$ by Nakayama's Lemma. Since the elements of B are permuted under the action of Q it follows that $\widehat{F}M_{1\times Q}$ is a permutation lattice.

Next, we shall show that $\widehat{P}M$ is a permutation lattice for $1 \times Q$ over R. Set $V = \widehat{P}M_{1\times Q}$. Write G as a disjoint union $G = \bigcup_i Pk_iU$ with $k_i \in G$ and set $B = \bigcup_i \{\widehat{P}k_ix \mid x \in Q\}$. Write s for the sum of the elements of some system of coset representatives of F in P, so that $\widehat{P} = \widehat{F}s$. We have $V \subseteq \widehat{F}M \cong R\bar{G}$, and treat the latter isomorphism as an identification. So $V = \bar{s}R\bar{G}$ and $B = \bigcup_i \{\bar{s}\bar{k_j}\bar{x} \mid x \in Q\}$. As above, it follows that B is an R-basis of V, the elements of which are permuted under the action of Q.

The lemma thus follows from Weiss' theorem [21, Theorem (50.1)]. $\square$

We are now in a position to prove Theorem B. We shall make use of the elementary theory of vertices and sources, the Krull-Schmidt Theorem and the Mackey decomposition. As a general reference we give [2].

Theorem 9. *If c is a unit in $\mathrm{V}(RG)$ of finite p-power order and $[N, c] = 1$, then $c \in N$.*

PROOF. Set $C = \langle c \rangle$, and consider M as $R(G \times N \times C)$-module, the action of $G \times N$ being given as before, and $m \cdot y = my$ for $m \in M$, $y \in C$.

Note that C acts trivially on $\widehat{N}M$. Indeed, $\widehat{N}M$ is a permutation module for C by Lemma 8 and C acts trivially on $\widehat{N}M/p\widehat{N}M$ by Proposition 1(a).

By Lemma 8,

$$M_{P\times N\times C} \;\cong\; \bigoplus_{j=1}^{n} 1\Big\uparrow_{U_j}^{P\times N\times C} \tag{4}$$

for some subgroups U_j of $P\times N\times C$. The number of summands equals the R-rank of the fixed point module $M^{P\times N\times C}$, which coincides with $M^{P\times 1\times 1}$ $(=\widehat{P}RG)$. Hence $n=|G:P|$. Since the modules $M_{P\times 1\times 1}$ and $M_{1\times N\times 1}$ are both free, it follows from (4) and Mackey decomposition that $U_j\cap(P\times 1\times 1)=1$ and $U_j\cap(1\times N\times 1)=1$ for all j. In particular, $|U_j|\le|N|\cdot|C|$ for all j, and comparing ranks in (4) gives $|U_j|=|N|\cdot|C|$ for all j. Restricting to $N\times N\times C$ in (4) gives

$$M_{N\times N\times C} \;\cong\; \bigoplus_{j=1}^{|G:P|} \bigoplus_{U_j(N\times N\times C)\backslash a} 1\Big\uparrow_{U_j^a\cap(N\times N\times C)}^{N\times N\times C}.$$

The number of summands in this decomposition is the R-rank of $M^{N\times N\times C}$. Since $M^{N\times N\times C}=M^{N\times 1\times 1}$ there are $|G:N|$ summands. It follows that $U_j\le N\times N\times C$ for all j. Hence $U_j=\{(x,(x\alpha_j)z_j^{-i},c^i)\mid x\in N, i\in\mathbb{Z}\}$ for some $z_j\in \mathrm{Z}(N)$ and $\alpha_j\in\mathrm{Aut}(N)$, and $1\Big\uparrow_{U_j}^{G\times N\times C}\Big\downarrow_{G\times N\times 1}$ is isomorphic to $1\Big\uparrow_{U_j\cap(G\times N\times 1)}^{G\times N\times 1}$, that is, to RG, the action given by $m\cdot(g,x,1)=g^{-1}m(x\alpha_j^{-1})$ for all $g\in G$, $x\in N$ and $m\in RG$. By Lemma 6, it follows that the modules $1\Big\uparrow_{U_j}^{G\times N\times C}$ are indecomposable. Since M is relatively $P\times N\times C$-projective, M is a direct summand of $M_{P\times N\times C}\Big\uparrow^{G\times N\times C}$, and by (4)

$$M_{P\times N\times C}\Big\uparrow^{G\times N\times C} \;\cong\; \bigoplus_{j=1}^{|G:P|} 1\Big\uparrow_{U_j}^{G\times N\times C}.$$

By Lemma 6, M is indecomposable, so it follows that $M\cong 1\Big\uparrow_{U_j}^{G\times N\times C}$ for some j. Since $(G\times 1\times 1)\cap U_j=1$, this shows that there is $u\in M$ such that Gu is an R-basis of M and $u=u\cdot(1,z_j^{-1},c)=uz_j^{-1}c$. It follows that u is a unit in RG and $c=z_j$. $\square$

Corollary 10. *If $x\in Q$ and $x\in 1+\mathrm{I}_R(N)G$ then $x\in N$.*

PROOF. For such an x we have $g_x\in N$ by Proposition 1(a), so $x\in N$ follows from Theorem 9, applied to $c=g_x^{-1}x\in \mathrm{C}_Q(N)$. $\square$

Lemma 11. *$M_{1\times Q}$ is a free RQ-module.*

PROOF. By Lemma 8, $M_{1\times Q}$ is a permutation lattice for Q over R. By Corollary 10, the kernel of the natural map $Q\to \mathrm{V}(RG/N)$ is N. By Proposi-

tion 1(a), an element x in Q acts on $\widehat{N}RG/p\widehat{N}RG$ by right multiplication with g_x. Since $N \leq Q$ and RG/N is free for the multiplication action of UN/N—recall that $U = \langle g_x \mid x \in Q\rangle$—it follows that $|Q| = |UN|$ and that each orbit of the action of Q on a basis of $M_{1\times Q}$ the elements of which it permutes has length $|Q|$. $\square$

Finally we prove Theorem A, again guided by the remarks from [10, p. 231].

Theorem 12. *There is a unit u of RG with $Q \leq P^u$ and $N = N^u$.*

PROOF. By Lemma 8,

$$M_{P\times Q} \;\cong\; \bigoplus_{k=1}^{l} 1\Big\uparrow_{V_k}^{P\times Q} \tag{5}$$

for some subgroups V_k of $P \times Q$. Since the modules $M_{P\times 1}$ and $M_{1\times Q}$ are both free (the latter by Lemma 11), it follows from Mackey decomposition that $V_k \cap (P \times 1) = 1$ and $V_k \cap (1 \times Q) = 1$ for all k. We shall show that the induced modules $1\big\uparrow_{V_k}^{G\times Q}$ are indecomposable. Mackey decomposition gives

$$M_{P\times N} \;\cong\; \bigoplus_{k=1}^{l} \bigoplus_{V_k\backslash a/P\times N} 1\Big\uparrow_{V_k^a\cap(P\times N)}^{P\times N}.$$

If $g_1, \ldots, g_{|G:P|}$ is a system of right coset representatives of P in G, then

$$M_{P\times N} \;\cong\; \bigoplus_{j=1}^{|G:P|} 1\Big\uparrow_{U_j}^{P\times N} \qquad \text{where } U_j = \{(n, n^{g_j}) \mid n \in N\}.$$

Let $1 \leq k \leq l$. From the above, it follows that there is $j = j(k)$ such that without lost of generality $V_k \cap (P\times N) = U_j$. In particular, $U_j \leq V_k$. Altogether, we see that there is a subgroup Q_k of Q containing N so that $V_k = \{(x\beta_k, x) \mid x \in Q_k\}$ for some injective homomorphism $\beta_k : Q_k \to P$. Hence the induced module $1\big\uparrow_{V_k}^{G\times Q_k}$ is isomorphic to the $R(G \times Q_k)$-module RG, the operation given by $m \cdot (g, x) = g^{-1}m(x\beta_k)$ for all $g \in G$, $x \in Q_k$ and $m \in RG$, and so is indecomposable by Lemma 6 since $N\beta_k = N$. Repeated application of Green's Indecomposability Theorem [2, (19.22)] now yields that $1\big\uparrow_{V_k}^{G\times Q}$ is indecomposable.

Since M is relatively $P \times Q$-projective, M is a direct summand of $M_{P\times Q}\big\uparrow^{G\times Q}$, and by (5)

$$M_{P\times Q}\Big\uparrow^{G\times Q} \;\cong\; \bigoplus_{k=1}^{l} 1\Big\uparrow_{V_k}^{G\times Q}.$$

By Lemma 6, M is indecomposable. Hence $M \cong 1\uparrow_{V_k}^{G\times Q}$ for some k. Comparing ranks shows that $Q_k = Q$. Since $V_k \cap (G \times 1) = 1$, this means that there is $u \in M$ such that Gu is an R-basis of M, i.e., u is a unit in RG, and $u = u \cdot (x\beta_k, x) = (x^{-1}\beta_k)ux$ for all $x \in Q$. In other words, $Q \leq P^u$ and $N = N^u$. $\square$
